

Cross-Asset Stock Ranking with a Mixture of Experts: Sector, Dynamic-KNN and Global-Factor Experts under a Regime Router

Model Research Report (Sample spec, PyTorch) — model_type: TimeSeries; dataset: real public US large-cap daily closes, 16 assets / 4 sectors / 256 trading days

1. Objective and model card

Implement a PyTorch mixture-of-experts (MoE) model for next-day cross-sectional stock ranking, and evaluate it on the real public dataset embedded in Appendix A: daily closing prices of 16 large-cap US stocks across 4 sectors (Technology, Financials, Healthcare, Energy), 256 trading days (source: Nasdaq public quote API, Aug 2025 - Aug 2026). Model card for the research pipeline:

```
model_name: StockMoEEExpertsModel
model_type: TimeSeries
description: Cross-asset ranking model. Encodes a trailing window of the full stock cross-section, mixes it temporally with a causal gated scan, and combines three experts - sector, dynamic-KNN and global-factor - through a regime router into a single return forecast for a target stock.
hyperparameters: hidden_dim D = 16; num_sectors S = 4; knn_neighbors K = 3; num_factors = 3
training_hyperparameters: n_epochs = 30; lr = 1e-3; early_stop = 10; batch_size = 256; weight_decay = 1e-4
```

2. Integration contract (mandatory)

The deliverable is ONE Python file named model.py containing exactly one class subclassing torch.nn.Module and the module-level assignment model_cls = StockMoEEExpertsModel. The class must satisfy this execution contract, which the automated runner applies verbatim:

```
import torch
from model import model_cls
m = model_cls(num_features=10, num_timesteps=4)
for _, param in m.named_parameters():
    param.data.fill_(1.0)
out = m(torch.full((32, 4, 10), 1.0))
assert out.shape == (32, 1) and torch.isfinite(out).all()
```

Consequences: (a) __init__(self, num_features, num_timesteps, **kwargs) - every other hyperparameter needs a default; (b) forward receives a float tensor of shape (batch_size, num_timesteps, num_features) and must return shape (batch_size, 1) - do NOT permute the input, timesteps are already axis 1; (c) after every nn.Parameter is overwritten with 1.0 and the input is a constant all-ones batch, forward must stay finite - no division by parameters, no BatchNorm (a constant batch has zero variance and produces NaN), prefer LayerNorm with eps or simple tanh/sigmoid gates; (d) fixed constants (masks, decay factors) should be register_buffer since buffers are NOT overwritten; (e) no side effects at import time (no file/network access, no dataset loading at module level), no try-except blocks, no top-level main; (f) the real-data demo of Section 8 must live inside an if __name__ == '__main__': guard. Only torch and the Python standard library may be imported.

3. Input convention of this model

Each row of a batch predicts ONE target stock on ONE day. A sample x in $\mathbb{R}^{(T \times F)}$ packs: columns 0 .. $A-1$ = trailing T -day daily log-return cross-section of A stocks (identical across samples that share a date), column A (the last column) = target indicator, constant along time with value $\text{target_idx} / (A - 1)$. Hence $F = A + 1$, i.e. $\text{num_features} = A + 1$. The model must work for ANY $\text{num_features} \geq 2$ and any num_timesteps : treat the last column as the target indicator, the remaining $A' = \text{num_features} - 1$ columns as the cross-section, and recover the target index as $\text{idx} = \text{clamp}(\text{round}(x[:, -1, -1] * (A' - 1)), 0, A' - 1).long()$. Under the acceptance test above, $A' = 9$ and $\text{idx} = 8$, which is valid.

4. Architecture

The model follows this diagram:

$x[B, T, F] \rightarrow$ Feature Encoder $\rightarrow$ Temporal gated scan $\rightarrow H[B, T, D]$
 $H + x \rightarrow$ three parallel experts E1 sector / E2 dynamic-KNN / E3 global-factor
 $(E1, E2, E3) +$ regime features $\rightarrow$ Regime Router gates $g1, g2, g3 \rightarrow y = \text{head}(\sum g_k E_k), \text{ shape } (B, 1)$

Feature Encoder (causal): $z_t = \tanh(\text{LayerNorm_eps}(x_t) W_e + b_e)$, W_e in $R^{(F \times D)}$, $D = 16$. Per-timestep, hence causal. Temporal mixer (Mamba-style gated scan, causal): $h_0 = 0$, $g_t = \text{sigmoid}(z_t W_g + b_g)$ in $[0, 1]^D$, $h_t = g_t * h_{t-1} + (1 - g_t) * z_t$. $H = \text{stack}(h_1 \dots h_T)$.

Expert 1 - Sector: split the A' cross-section columns into $S = \min(4, A')$ consecutive blocks (a stand-in for the GICS hierarchy; in the demo data columns are already ordered by sector). Compute per-block means over the last $\min(3, T)$ timesteps $\rightarrow s$ in R^S . Target block $ts = \text{idx} // \text{ceil}(A'/S)$, clamped. $E1 = \text{Linear}(2S \rightarrow 1)(\text{concat}(s, s * \text{onehot}(ts)))$.

Expert 2 - Dynamic KNN: gather the target series $xs = x[:, :, \text{idx}]$. Compute trailing Pearson correlation of xs with every other column over the window T ($\text{cov} / (\text{std}_i * \text{std}_j + \text{eps})$), $\tanh$ -compress, keep top $K = \min(3, A'-1)$ with softmax weights w . $E2 = \text{Linear}(1 \rightarrow 1)(\sum_j w_j * x[:, -1, j])$ - a correlation-weighted readout of the neighbors' most recent moves, so the effective predictor tracks the changing correlation structure.

Expert 3 - Global factor: $M = x[:, :, :A']$ centered over the time axis; $\text{torch.linalg.svd}(M) \rightarrow$ keep top-3 singular values $s3$ ($B, 3$) and right vectors $V3$ ($B, A', 3$); target loading $l = V3[\text{range}(B), \text{idx}, :3]$; $E3 = \text{Linear}(3 \rightarrow 1)(l * (s3 / (s3.\text{max} + \text{eps})))$.

Regime Router: regime features ϕ in R^3 computed from x (data-driven, no parameters): realized vol of the cross-section mean series, trailing momentum (window mean of the cross-section mean), cross-sectional dispersion at the last timestep; z-score each within the window with eps . Gates $g = \text{softmax}(\phi W_r + b_r)$ in R^3 . Output head: $y = \text{Linear}(1 \rightarrow 1)(g1 * E1 + g2 * E2 + g3 * E3)$, returned as $(B, 1)$.

5. Stability requirements

Every denominator gets $+ \text{eps}$ ($1e-6$). torch.linalg.svd must receive the centered matrix of a constant batch without NaN: centering makes it exactly zero, which is fine. All gather/scatter indices are clamped to valid ranges. No BatchNorm1d/2d . The model must produce a finite $(B, 1)$ tensor for the all-ones, all-parameters-1.0 acceptance test of Section 2.

6. Data and splits (demo, strictly causal)

Parse the Appendix A CSV: first column Date, remaining headers 'Sector:TICKER' (16 columns). Build price matrix P (256×16) and daily log returns R . Window length $T_{\text{win}} = 20$; horizon 1 day: target $y[t, a] = R[t+1, a]$. Samples: for every usable date t and stock a , x packs $R[t-T_{\text{win}}+1 \dots t, :]$ plus target indicator $a/(16-1)$. Split by date: first 60% train, next 20% validation, last 20% test. All statistics causal. Nothing is fitted on test except evaluation.

7. Training

$\text{torch.manual_seed}(7)$. Adam, $\text{lr} = 1e-3$, $\text{weight_decay} = 1e-4$, $\text{batch_size} = 256$, at most $n_{\text{epochs}} = 30$ with early stopping (patience 10) on validation MSE of the next-day target return. CPU only, no network, total runtime under 10 minutes.

8. Evaluation protocol (inside the `__main__` guard)

Embed the Appendix A CSV as a string constant INSIDE the `__main__` guard of `model.py` (the file is still importable side-effect-free). On the test split report per date the Spearman rank IC between predicted and realized next-day returns, averaged over dates, and the long-short return (mean of top-3 minus bottom-3 predicted stocks per date, bps/day). Also report ablations with the router gates fixed: expert-1-only, expert-2-only, expert-3-only, and equal-weight 1/3 each. Print a small results table.

9. Reference results (feasibility baseline, NumPy prototype, seed 7)

A closed-form NumPy prototype of this exact architecture on this dataset achieved on the 51 test days: rank IC MoE $+0.0062$ vs equal-weight -0.0252 vs experts alone -0.0015 / -0.0396 / -0.0441 ; long-short $+8.12$ bps/day vs -23.51 for equal weight; learned gates $[0.18, 0.71, 0.12]$ (sector / KNN / factor). A torch implementation with a short training loop

should reach comparable or better rank IC; matching the sign and relative ordering is sufficient for this sample.

10. Constraints and report format

Deterministic (seed 7), torch + stdlib only, no network, runtime < 10 min. The final report should restate the architecture, the acceptance-test result, the results table of Section 8, and one paragraph of analysis of the learned router gates.

Appendix A - Embedded dataset (CSV, parse this text)

Columns are 'Sector:TICKER'. Embed this CSV as a string constant inside the __main__ guard of model.py and parse it there. No network access is allowed anywhere.
